Amplitude Representation

► Amplitude representation of a sine curve

$$s(t) = A \sin(2\pi f t + \phi)$$

- A: amplitude
- ϕ : phase shift
- f: frequency = 1/T
- T: time period

Fourier Transformation

► Fourier transformation of a periodic function

- decomposition in various sine and cosine functions

► Dirichlet condition of a periodic function f

- $f(x) = f(x+2\pi)$
- $f(x)$ in $(-\pi, \pi)$ in finitely many intervals continuous and monotonic
- If f is discontinuous at x_0 , then $f(x_0) = (f(x_0-0) + f(x_0+0))/2$

► Theorem of Dirichlet:

- If $f(x)$ satisfies $(-\pi, \pi)$ the Dirichlet condition then there exists Fourier coefficients $a_0, a_1, a_2, \dots, b_1, b_2, \dots$ such that

$$\lim_{n \rightarrow \infty} \frac{a_0}{2} + \sum_{k=1}^n a_k \cos kx + b_k \sin kx = f(x) .$$

Computation of Fourier Coefficients

► Fourier coefficients a_k, b_k :

- For $k = 0, 1, 2, \dots$

$$a_k = \frac{1}{\pi} \int_{-\pi}^{\pi} f(x) \cos kx \, dx$$

- For $k = 1, 2, 3, \dots$

$$b_k = \frac{1}{\pi} \int_{-\pi}^{\pi} f(x) \sin kx \, dx$$

► Example: saw tooth curve

$$f(x) = x, \text{ für } 0 < x < 2\pi$$

$$f(x) = \pi - 2 \left(\frac{\sin x}{1} + \frac{\sin 2x}{2} + \frac{\sin 3x}{3} + \dots \right)$$

Fourier Analysis for general period

► **Theorem of Fourier for period $T=1/f$:**

- The coefficients c , a_n , b_n are then obtained as follows

$$g(t) = \frac{a_0}{2} + \sum_{k=1}^{\infty} a_k \cos(2\pi k f t) + b_k \sin(2\pi k f t)$$

$$a_k = \frac{2}{T} \int_0^T g(t) \cos(2\pi n f t) dt$$

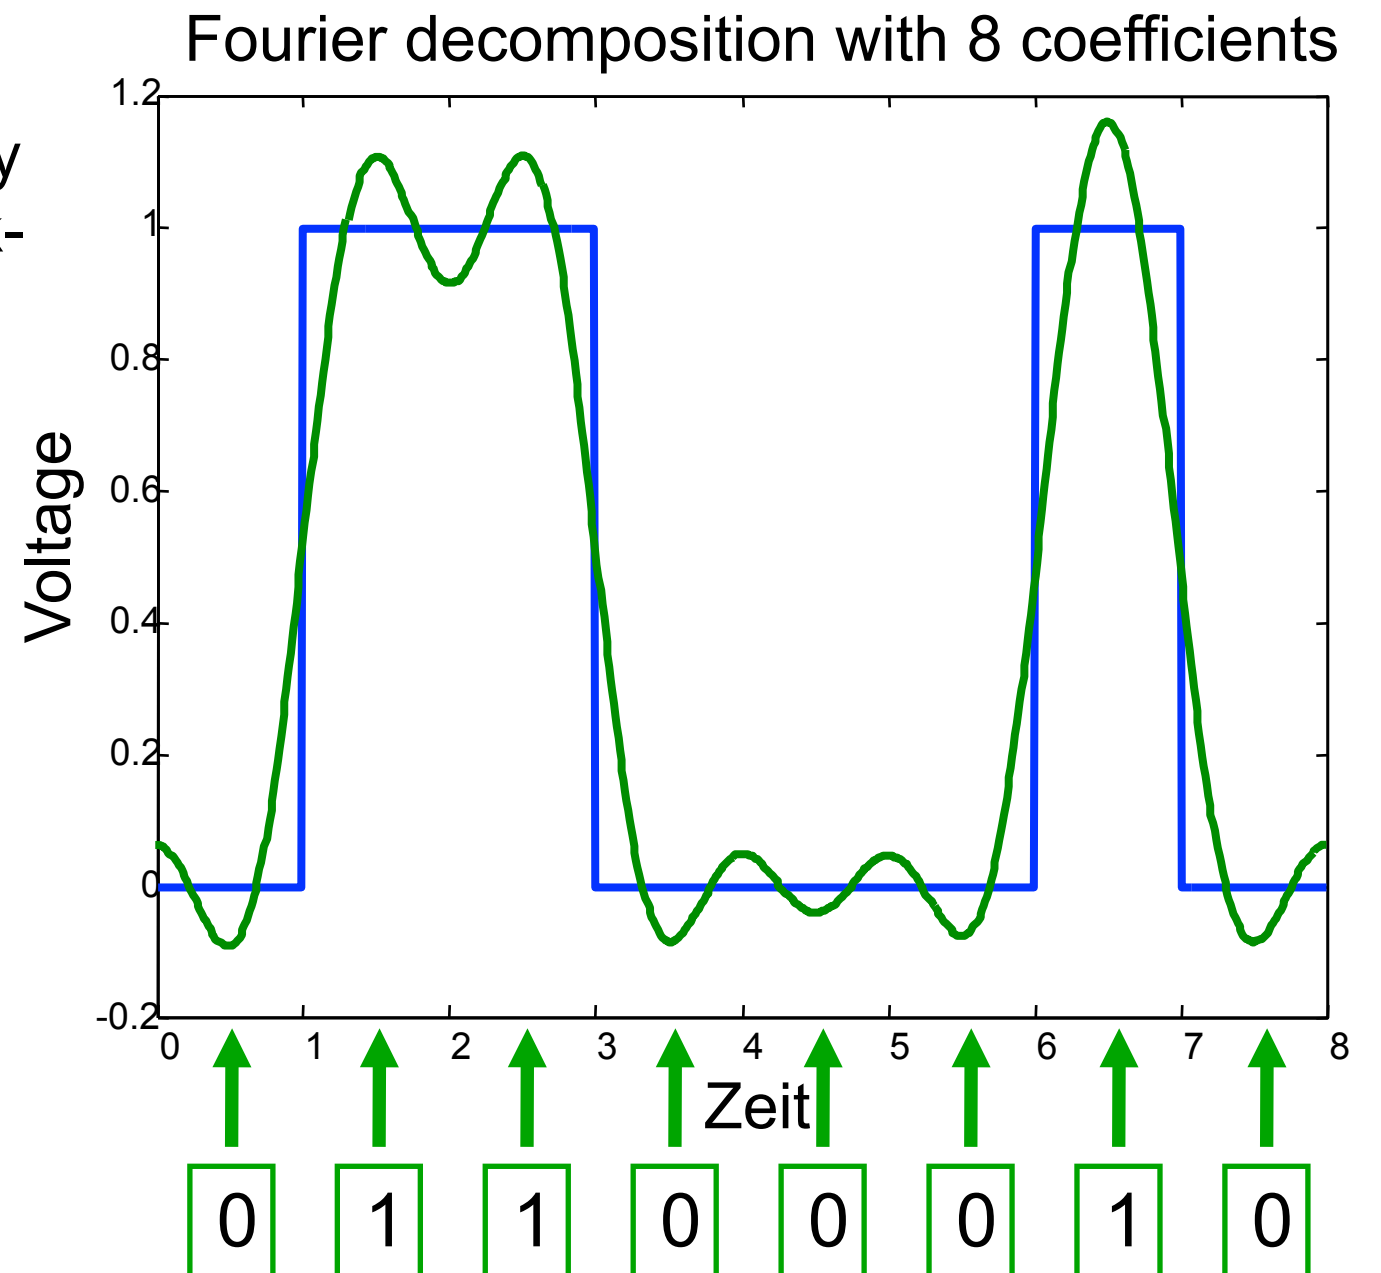

$$b_k = \frac{2}{T} \int_0^T g(t) \sin(2\pi n f t) dt$$

- **The sum of squares of the k -th terms is proportional to the energy consumed in this frequency:**

$$(a_k)^2 + (b_k)^2$$

How often do you measure?

- ▶ How many measurements are necessary to determine a Fourier transform to the k -th component, exactly?
- ▶ **Nyquist-Shannon sampling theorem**
 - To reconstruct a continuous band-limited signal with a maximum frequency f_{\max} you need at least a sampling frequency f_{\max} of $2 f_{\max}$.

Symbols and Bits

► For data transmission instead of bits can also be used symbols

- E.g. 4 Symbols: A, B, C, D with
 - A = 00, B = 01, C = 10, D = 11

► Symbols

- Measured in baud
- Number of symbols per second

► Data rate

- Measured in bits per second (bit / s)
- Number of bits per second

► Example

- 2400 bit/s modem is 600 baud (uses 16 symbols)

Structure of a broadband digital transmission

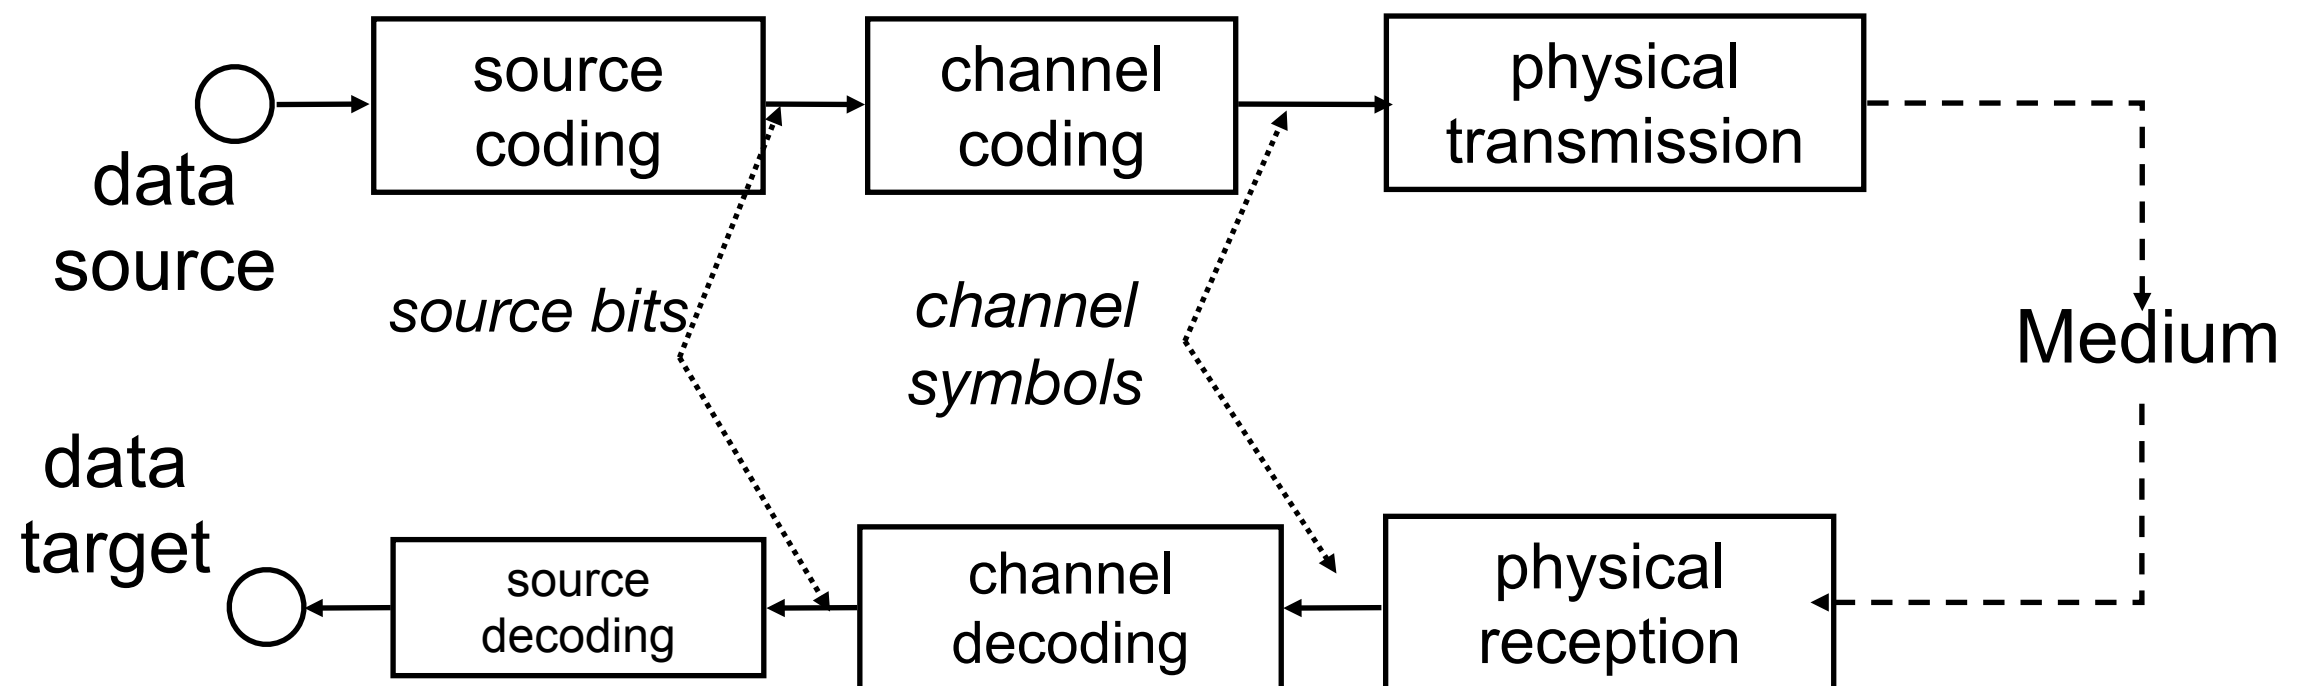

► Source Coding

- removing redundant or irrelevant information
- e.g. with lossy compression (MP3, MPEG 4)
- or with lossless compression (Huffman code)

► Channel Coding

- Mapping of source bits to channel symbols
- Possibly adding redundancy adapted to the channel characteristics
- physical transmission

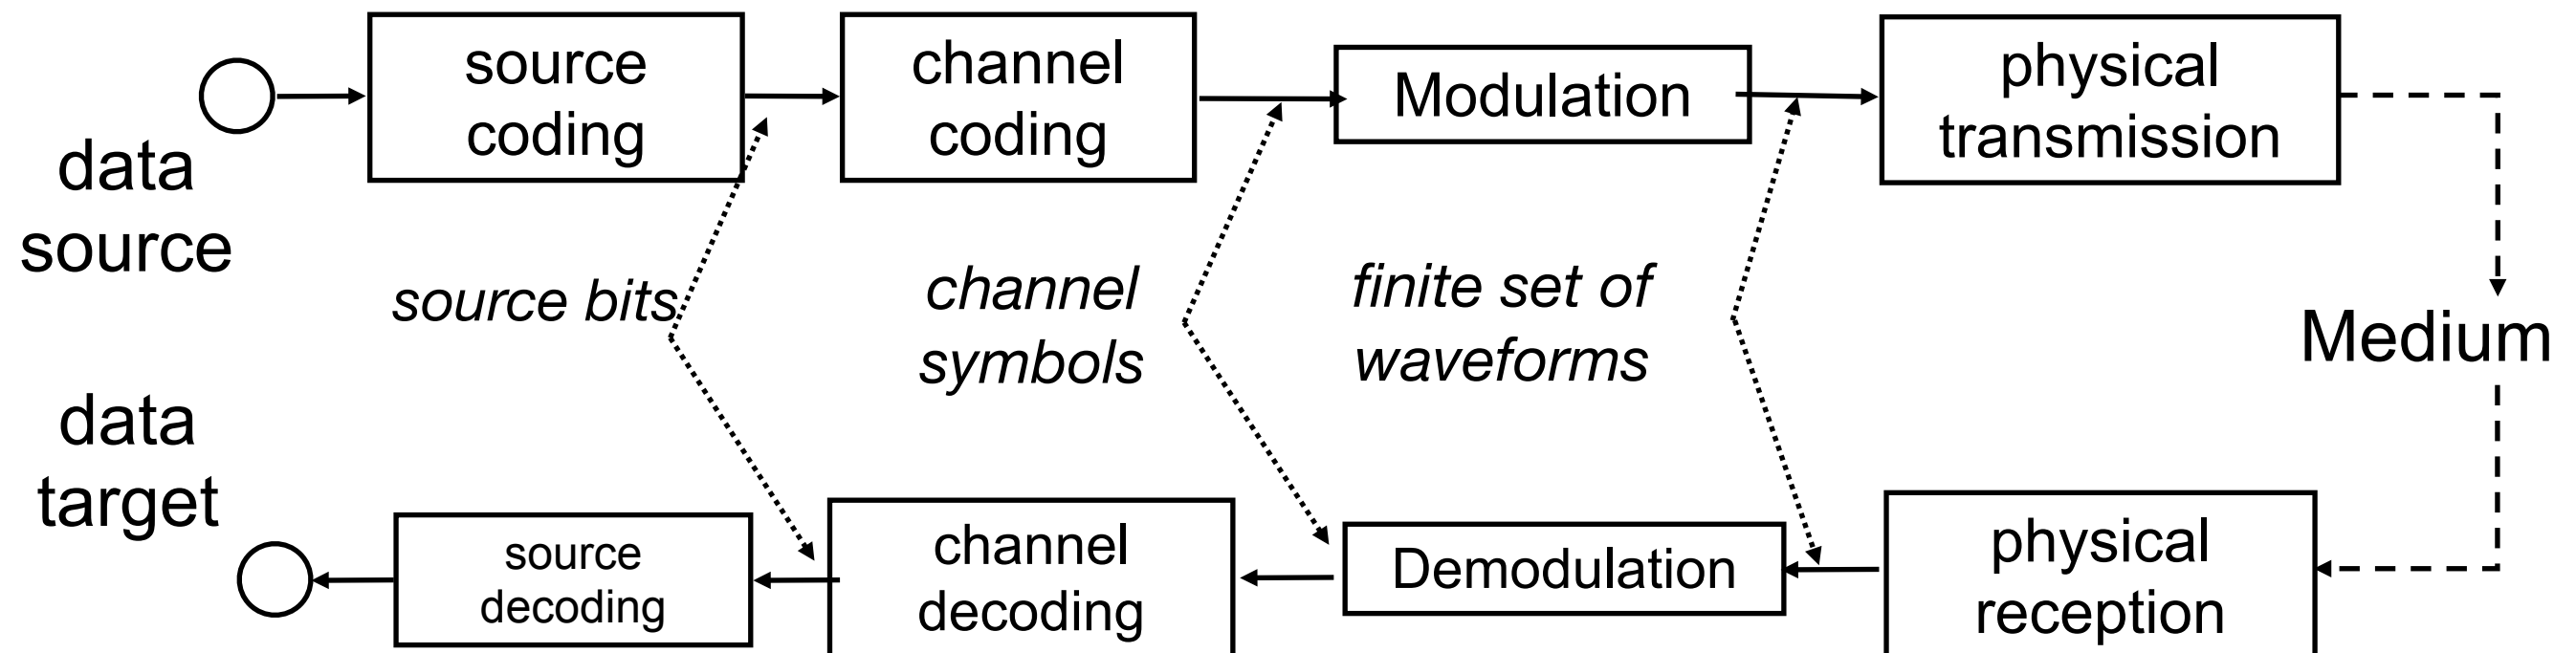

► Conversion into physical events

Structure of a broadband digital transmission

► MOfulation/DEModulation

- Translation of the channel symbols by
 - amplitude modulation
 - phase modulation
 - frequency modulation
 - or a combination thereof

Broadband

► Idea

- Focusing on the ideal frequency of the medium
- Using a sine wave as the carrier wave signals

► A sine wave has no information

- the sine curve continuously (modulated) changes for data transmission,
- implies spectral widening (more frequencies in the Fourier analysis)

► The following parameters can be changed:

- Amplitude A
- Frequency $f=1/T$
- Phase ϕ

$$s(t) = A \sin(2\pi f t + \phi)$$

Amplitude Modulation

- ▶ The time-varying signal $s(t)$ is encoded as the amplitude of a sine curve:

$$f_A(t) = s(t) \sin(2\pi ft + \phi)$$

- ▶ **Analoges Signal**

- analog signal
- amplitude modulation
- Continuous function in time
- e.g. second prolonged wave signal (sound waves)

- ▶ **Digital signal**

- amplitude keying
- E.g. given by symbols as a symbol of strength
- special case: symbols 0 or 1
 - on / off keying

Amplitude Shift Keying (ASK)

- ▶ Let $E_i(t)$ is the symbol energy at time t

$$s_i(t) = \sqrt{\frac{2E_i(t)}{T}} \cdot \sin(\omega_0 t + \phi)$$

- ▶ Example: $E_0(t) = 1$, $E_1(t) = 2$

Frequency Modulation

- ▶ The time-varying signal $s(t)$ is encoded in the frequency of the sine curve:

$$f_F(t) = a \sin(2\pi s(t)t + \phi)$$

- ▶ **Analog signal**

- Frequency modulation (FM)
- Continuous function in time

- ▶ **Digital signal**

- Frequency Shift Keying (FSK)
- E.g. frequencies as given by symbols

Frequency Shift Keying (FSK)

► Frequency signals $\omega_i(t)$

$$s_i(t) = \sqrt{\frac{2E}{T}} \cdot \sin(\omega_i(t) \cdot t + \phi)$$

► Example:

Phase Modulation

- The time-varying signal $s(t)$ is encoded in the phase of the sine curve:

$$f_P(t) = a \sin(2\pi ft + s(t))$$

- **Analog signal**

- phase modulation (PM)
- very unfavorable properties
- es not used

- **Digital signal**

- phase-shift keying (PSK)
- e.g. given by symbols as phases

Digital and analog signals in comparison

- ▶ **For a station there are two options**
 - digital transmission
 - finite set of discrete signals
 - e.g. finite amount of voltage sizes / voltages
 - analog transmission
 - Infinite (continuous) set of signals
 - E.g. Current or voltage signal corresponding to the wire
- ▶ **Advantage of digital signals:**
 - There is the possibility of receiving inaccuracies to repair and reconstruct the original signal
 - Any errors that occur in the analog transmission may increase further

Phase Shift Keying (PSK)

► For phase signals $\phi_i(t)$

$$s_i(t) = \sqrt{\frac{2E}{T}} \cdot \sin(\omega_0 t + \phi_i(t))$$

► Example:

PSK with different symbols

- ▶ **Phase shifts can be detected by the receiver very well**
- ▶ **Encoding various Symbols very simple**
 - Using phase shift e.g. $\pi / 4$, $3/4\pi$, $5/4\pi$, $7/4\pi$
 - rarely: phase shift 0 (because of synchronization)
 - For four symbols, the data rate is twice as large as the symbol rate
- ▶ **This method is called Quadrature Phase Shift Keying (QPSK)**

Amplitude and phase modulation

- ▶ **Amplitude and phase modulation can be successfully combined**
 - Example: 16-QAM (Quadrature Amplitude Modulation)
 - uses 16 different combinations of phases and amplitudes for each symbol
 - Each symbol encodes four bits ($2^4 = 16$)
 - The data rate is four times as large as the symbol rate

Nyquist's Theorem

► Definition

- The band width H is the maximum frequency in the Fourier decomposition

► Assume

- The maximum frequency of the received signal is $f = H$ in the Fourier transform
 - (Complete absorption [infinite attenuation] all higher frequencies)
- The number of different symbols used is V
- No other interference, distortion or attenuation of

► Nyquist theorem

- The maximum symbol rate is at most $2 H$ baud.
- The maximum possible data rate is a bit more than $2 \log_2 H V / s$.

Do more symbols help?

- ▶ **Nyquist's theorem states that could theoretically be increased data rate with the number of symbols used**
- ▶ **Discussion:**
 - Nyquist's theorem provides a theoretical upper bound and no method of transmission
 - In practice there are limitations in the accuracy
 - Nyquist's theorem does not consider the problem of noise

The Theorem of Shannon

- ▶ **Indeed, the influence of the noise is fundamental**
 - Consider the relationship between transmission intensity S to the strength of the noise N
 - The less noise the more signals can be better recognized
- ▶ **Theorem of Shannon**
 - The maximum possible data rate is $H \log_2 (1 + S / N)$ bits / s
 - with bandwidth H
 - Signal strength S
- ▶ **Attention**
 - This is a theoretical upper bound
 - Existing codes do not reach this value

Bit Error Rate and SINR

- ▶ **Higher SINR decreases Bit Error Rate (BER)**
 - BER is the rate of faulty received bits
- ▶ **Depends from the**
 - signal strength
 - noise
 - bandwidth
 - encoding
- ▶ **Relationship of BER and SINR**
 - Example: 4 QAM, 16 QAM, 64 QAM, 256 QAM
