

Peer-to-Peer Networks 03 CAN (Content Addressable Network)

JNI FREIBURG

Christian Ortolf Technical Faculty Computer-Networks and Telematics University of Freiburg

CAN Playground

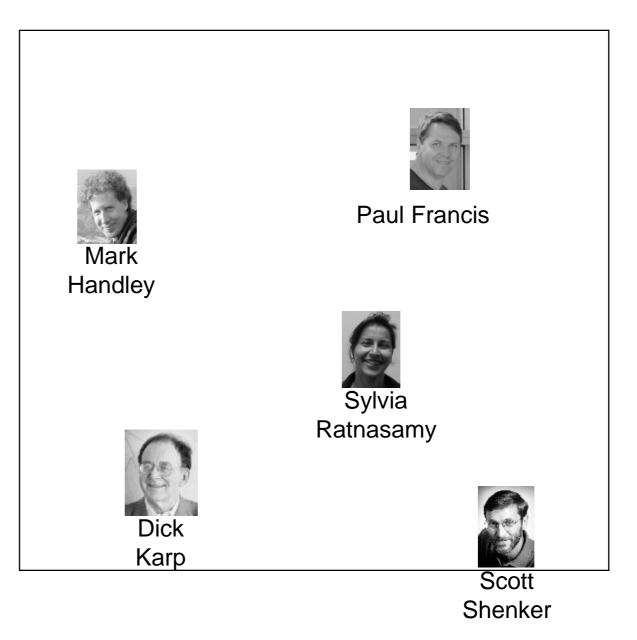

- Index entries are mapped to the square [0,1]²
 - using two hash functions to the real numbers
 - according to the search key
- Assumption:
 - hash functions
 behave a like a
 random
 mapping

CAN Index Entries

- Index entries are mapped to the square [0,1[^2
 - using two hash functions to the real numbers
 - according to the search key
- Assumption:
 - hash functions behave a like a random mapping
- Literature
 - Ratnasamy, S., Francis, P., Handley, M., Karp, R., Shenker, S.: A scalable contentaddressable network. In: Computer Communication Review. Volume 31., Dept. of Elec. Eng. and Comp. Sci., University of California, Berkeley (2001) 161–172

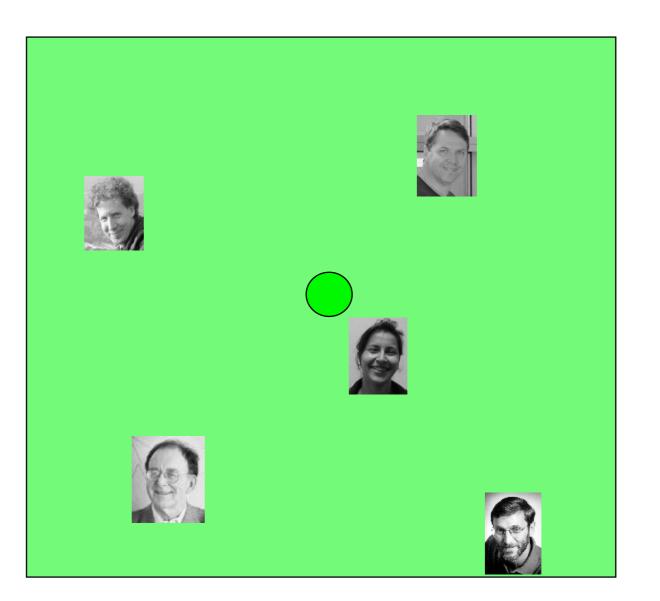

First Peer in CAN

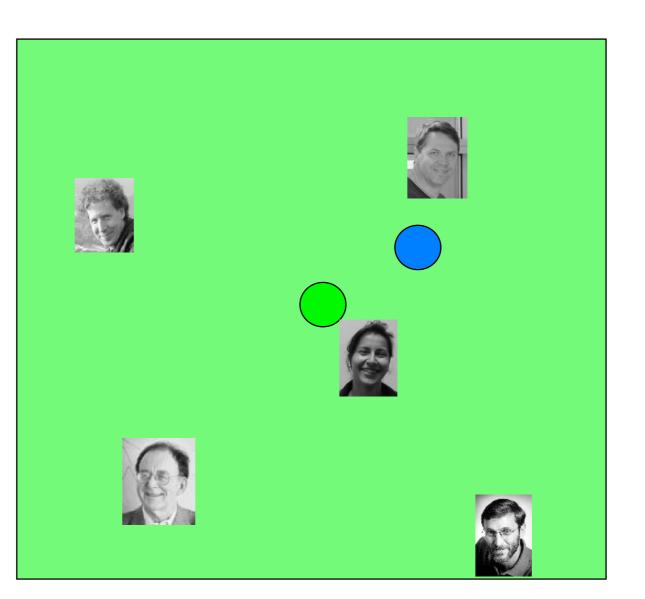

- In the beginning there is one peer owning the whole square
- All data is assigned to the (green) peer

CAN: The 2nd Peer Arrives

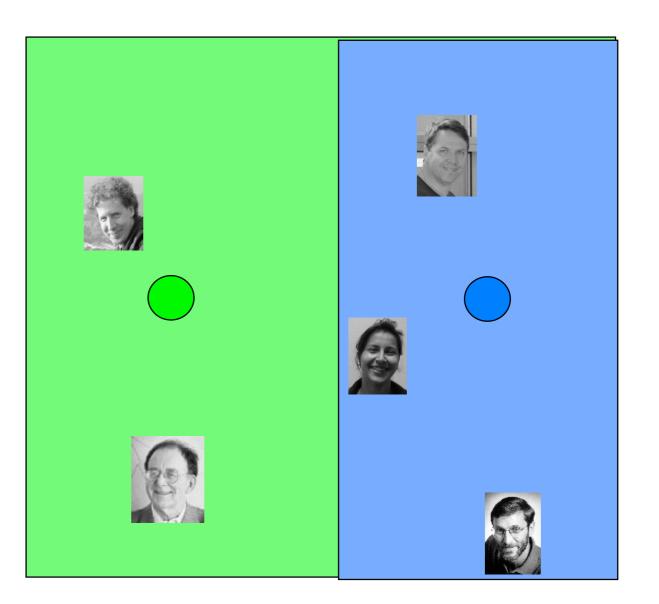

- The new peer chooses a random point in the square
 - or uses a hash function applied to the peers Internet address
- The peer looks up the owner of the point
 - and contacts the owner

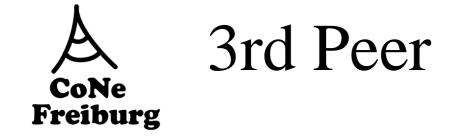

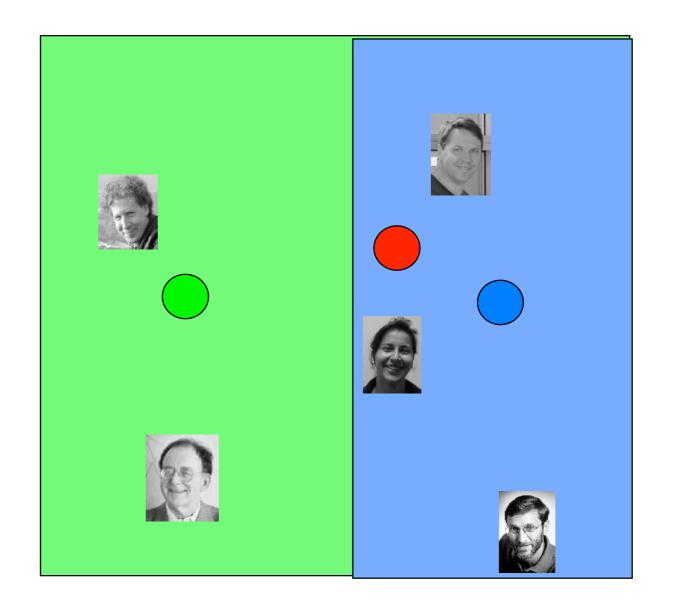

CAN: 2nd Peer Has Settled Down

- The new peer chooses a random point in the square
 - or uses a hash function applied to the peers Internet address
- The peer looks up the owner of the point
 - and contacts the owner
- The original owner divides his rectangle in the middle and shares the data with the new peer

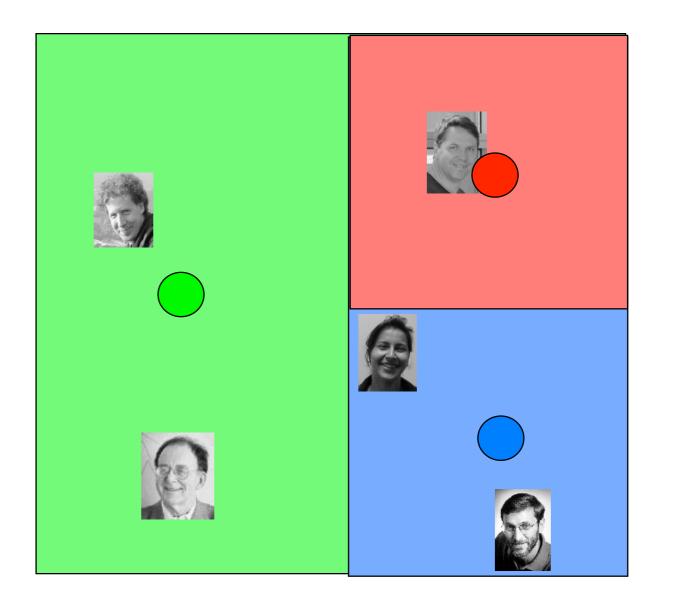

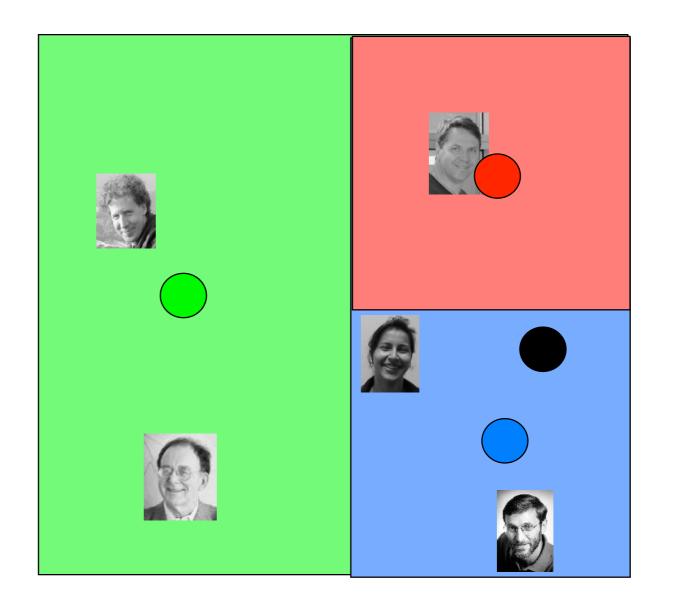

CAN: 3rd Peer

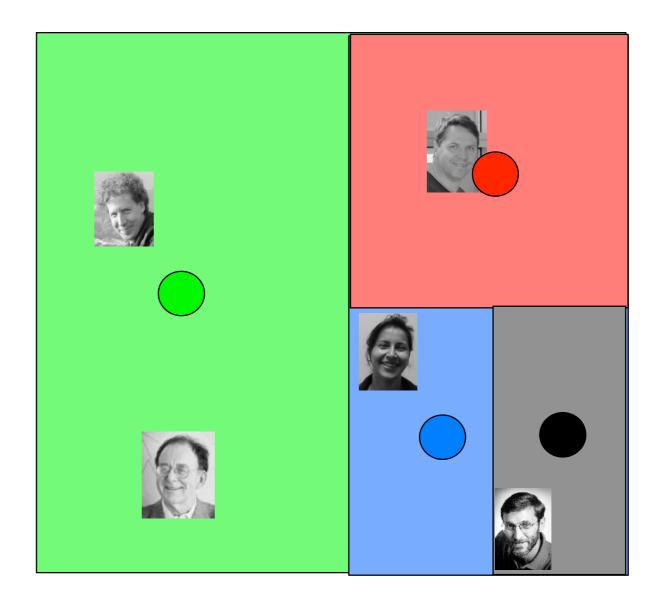

CAN: 4th Peer

CAN: 4th Peer Added

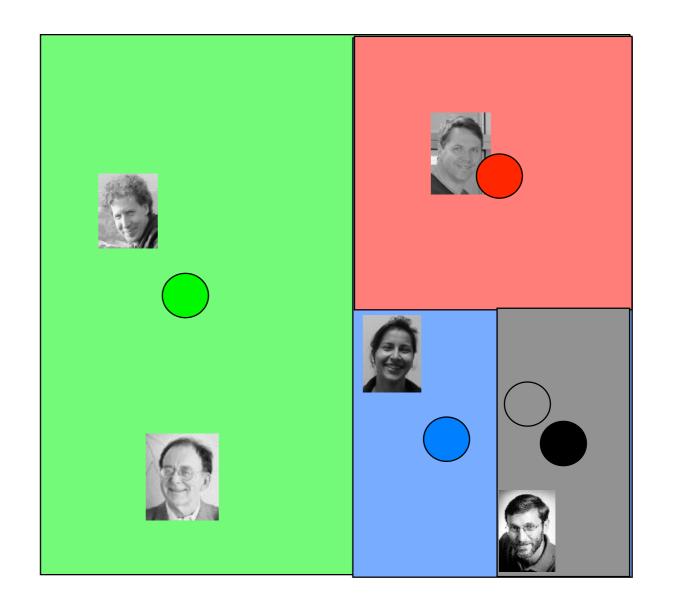

10

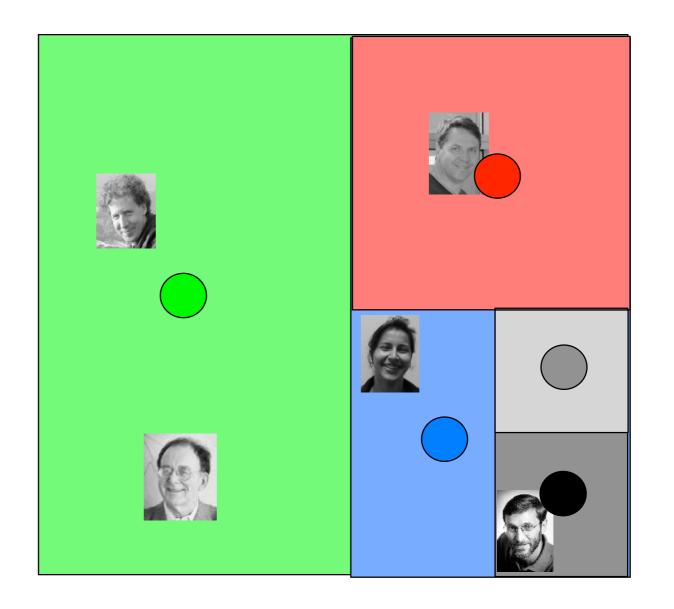

CAN: 5th Peer

CAN: All Peers Added

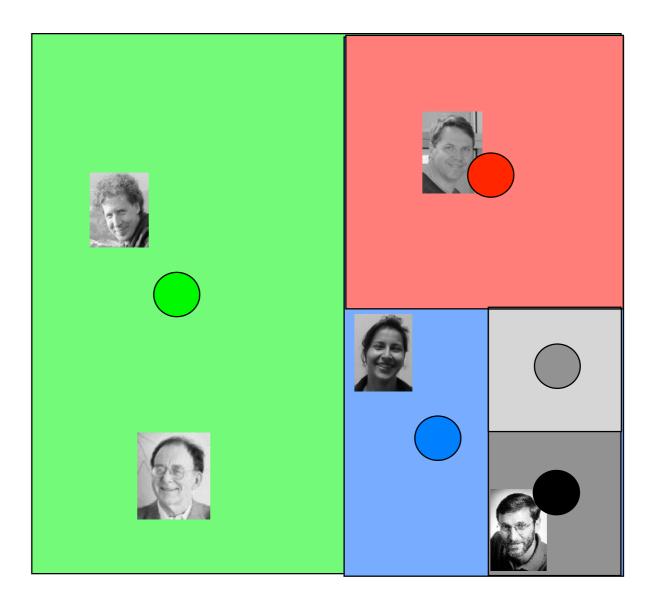

On the Size of a Peer's Area

- R(p): rectangle of peer p
- A(p): area of the R(p)
- n: number of peers
- area of playground square: 1
- Lemma
 - For all peers we have

$$E[A(p)] = \frac{1}{n}$$

- Lemma
 - Let P_{R,n} denote the probability that no peers falls into an area R. Then we have

 $P_{R,n} \le e^{-n\operatorname{Vol}(R)}$

An Area Not being Hit

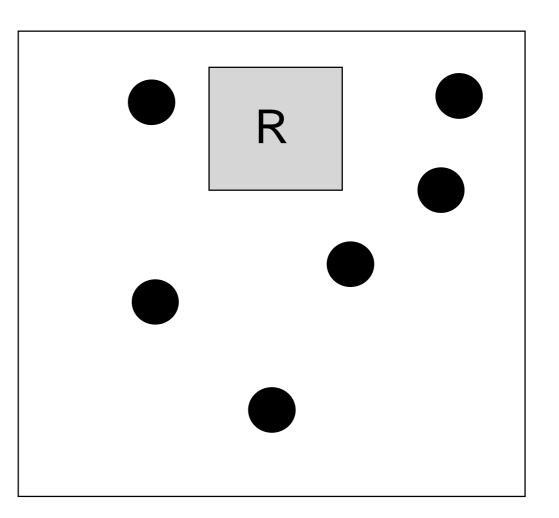

Lemma

- Let $P_{R,n}$ denote the probability that no peers falls into an area R. Then $P_{R,n} \leq e^{-n \operatorname{Vol}(R)}$
- Proof
 - Let x=Vol(R)
 - The probability that a peer does not fall into R is 1 x
 - The probability that n peers do not fall into R is $(1-x)^n$
 - So, the probability is bounded by

$$m > 1 : \left(1 - \frac{1}{m}\right)^m \le \frac{1}{e}$$

- because

$$(1-x)^n = ((1-x)^{\frac{1}{x}})^{nx} \le e^{-nx}$$

How Fair Are the Data Balanced

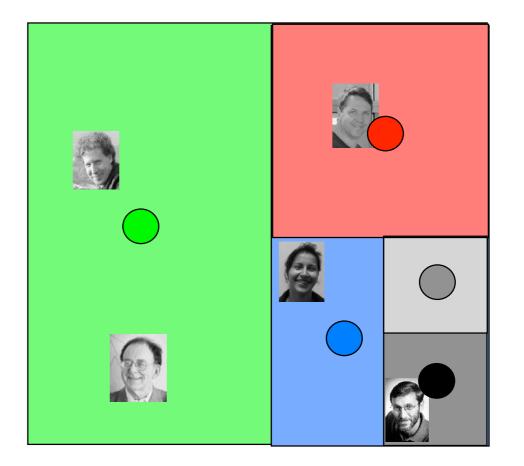

- Lemma
 - With probability n^{-c} a rectangle of size (c ln n)/n is not further divided
- Proof
 - Let P_{R,n} denote the probability that no peers falls into an area R. Then we have

 $P_{R,n} \le e^{-n\operatorname{Vol}(R)}$

- Every peer receives at most c (ln n) m/n elements
 - if all m elements are stored equally distributed over the area
- While the average peer stores m/n elements

 $P_{R,n} \le e^{-n\frac{c\ln n}{n}} = e^{-c\ln n} = n^{-c}$

 So, the number of data stored on a peer is bounded by c (In n) times the average amount

Network Structure of CAN

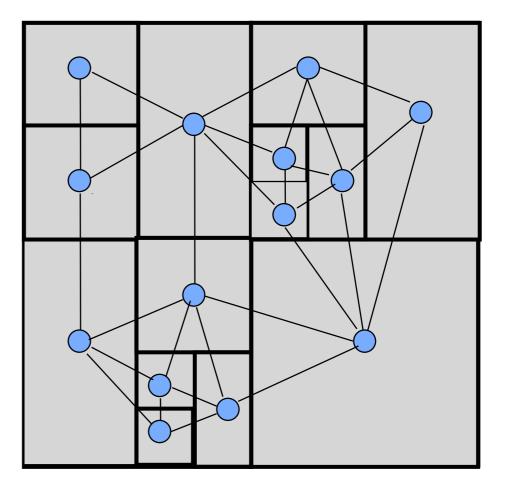

- Let d be the dimension of the square, cube, hyper-cube
 - 1: line
 - 2: square
 - 3: cube
 - 4: ...
- Peers connect
 - if the areas of peers share a (d-1)-dimensional area
 - e.g. for d=2 if the rectangles touch by more than a point

Lookup in CAN

- Compute the position of the index using the hash function on the key value
- Forward lookup to the neighbored peer which is closer to the index
- Expected number of hops for CAN in d dimensions: O(n^{1/d})
- Average degree of a node
 O(d)

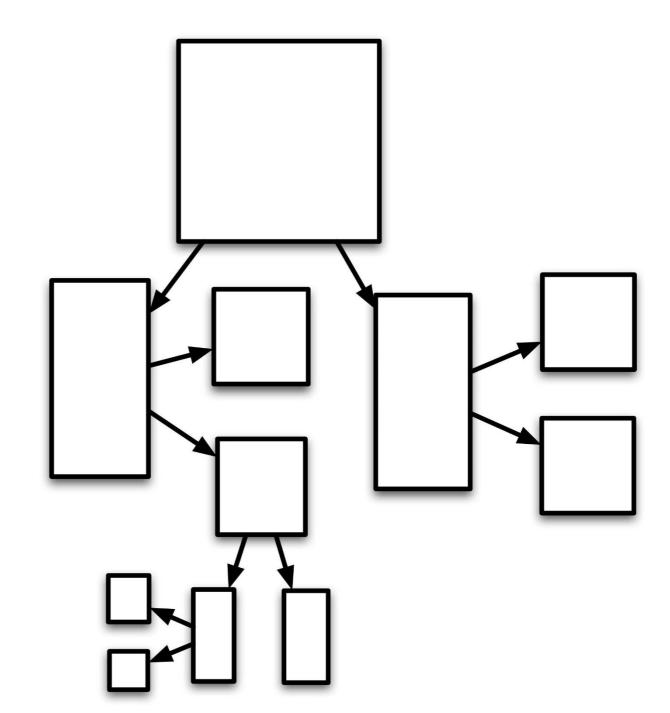

Insertions in CAN = Random Tree

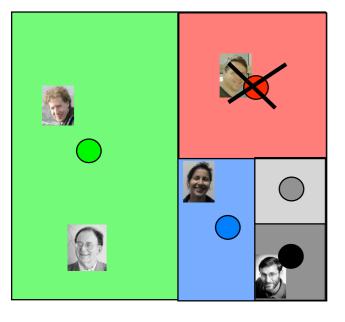

- Random Tree
 - new leaves are inserted randomly
 - if node is internal then flip coin to forward to left or right sub-tree
 - if node is leaf then insert two leafs to this node
- Depth of Tree
 - in the expectation: O(log n)
 - Depth O(log n) with high probability, i.e. 1-n^{-c}
- Observation
 - CAN inserts new peers like leafs in a random tree

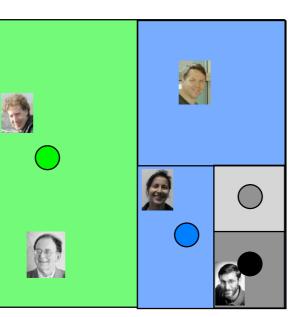

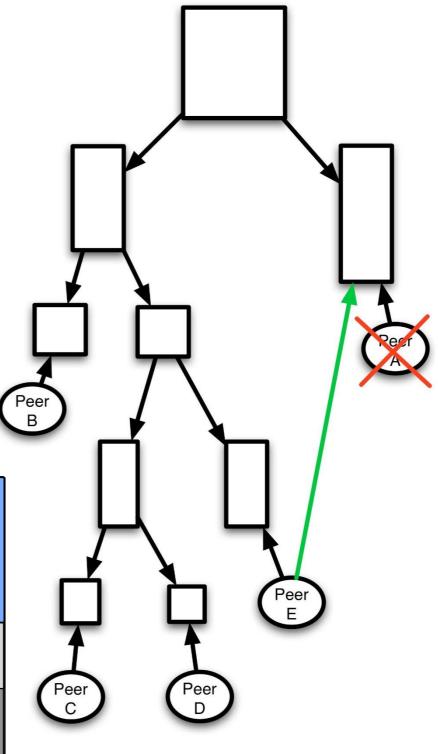

Leaving Peers in CAN

- If a peer leafs
 - he does not announce it
- Neighbors continue testing on the neighborhood
 - to find out whether peer has left
 - the first neighboir who finds a missing neighbor takes over the area of the missing peer
- Peers can be responsible for many rectangles
- Repeated insertions and deletions of peers leed to fragmentation

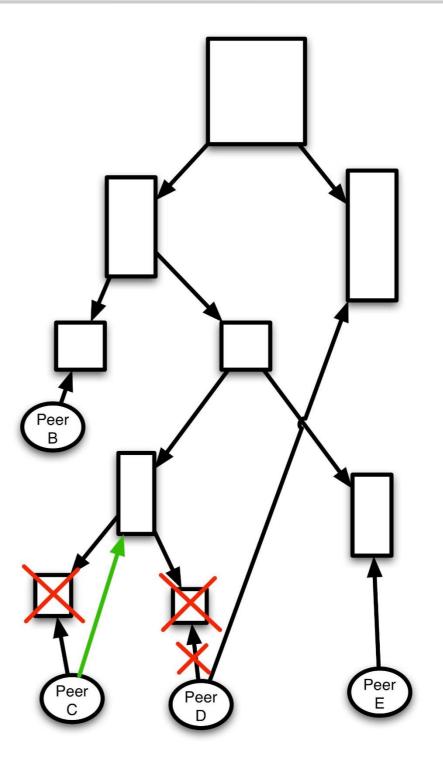

Defragmentation — The Simple Case

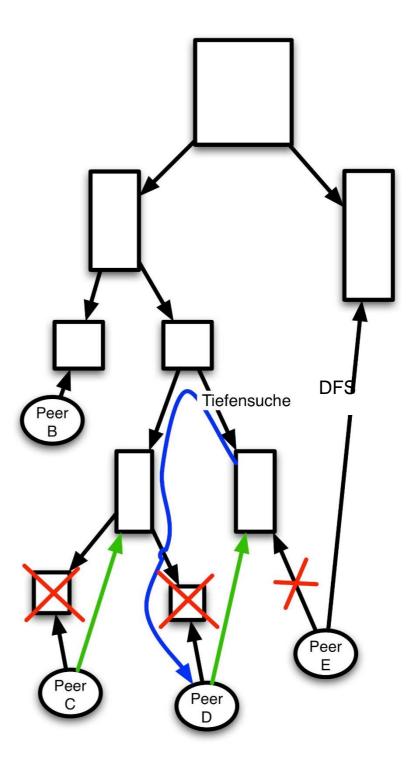

- To heal fragmented areas
 - from time to to time areas are freshly assigned
- Every peer with at least two zones
 - erases smalles zone
 - finds replacement peer for this zone
- 1st case: neighboring zone is undivided
 - both peers are leafs in the random tree
 - transfer zone to the neighbor

Defragmentation — The Difficult Case

- Every peer with at least two zones
 - erases smalles zone
 - finds replacement peer for this zone
- Ind case: neighboring zone is further divided
 - Perform DFS (depth first search) in neighbor tree until two neighbored leafs are found
 - Transfer the zone to one leaf which gives up his zone
 - Choose the other leaf to receive the latter zone

INI

Improvements for CAN

- More dimensions
- Multiples realities
- Distance metric for routing
- Overloading of zones
- Multiple hasing
- Topology adapted network construction
- Fairer partitioning
- Caching, replication and hot-spot management

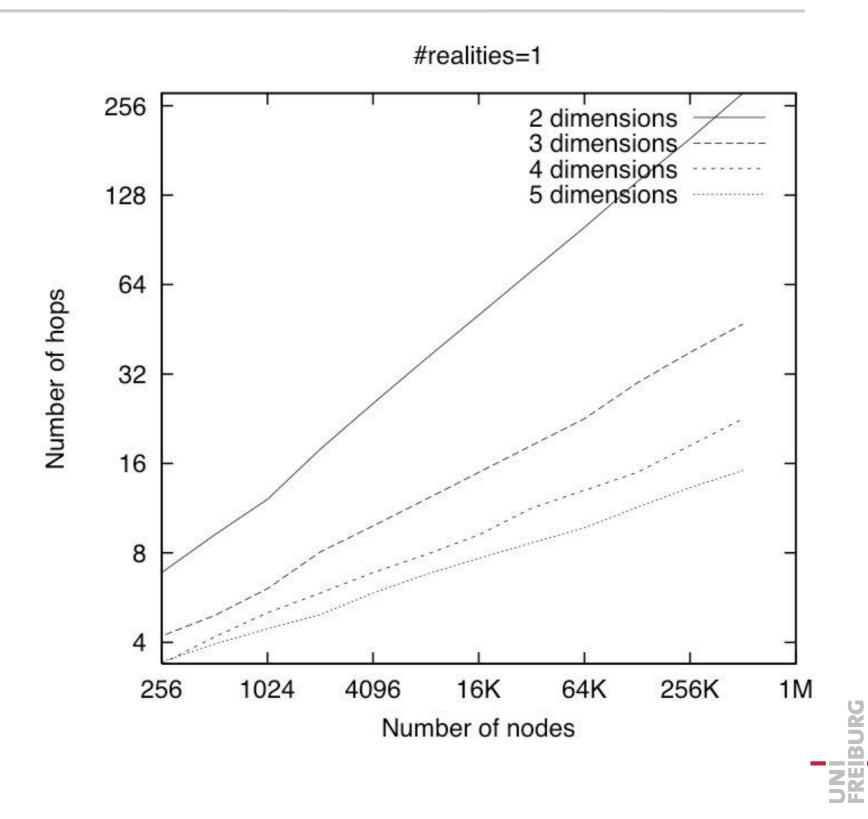

CoNe Freiburg

Higher Dimensions

- Let d be the dimension of the square, cube, hypercube
 - 1: line
 - 2: square
 - 3: cube
 - 4: ...

 The expected path length is O(n^{1/d})

 Average number of neighbors O(d)

More Realities

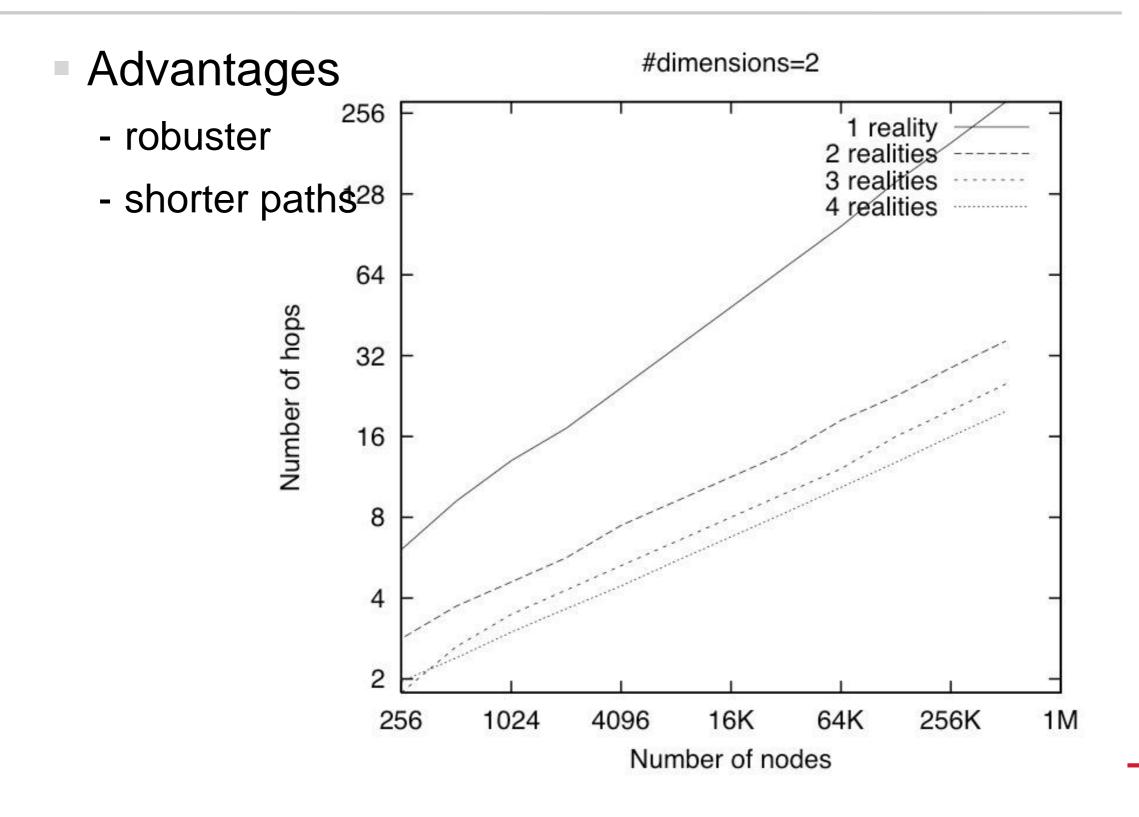

- Build simultanously r CANs with the same peers
- Each CAN is called a *reality*
- For lookup
 - greedily jump between realities
 - choose reality with the closest distance to the target
- Advantanges
 - robuster network
 - faster search

INI Reiburg

More Realities

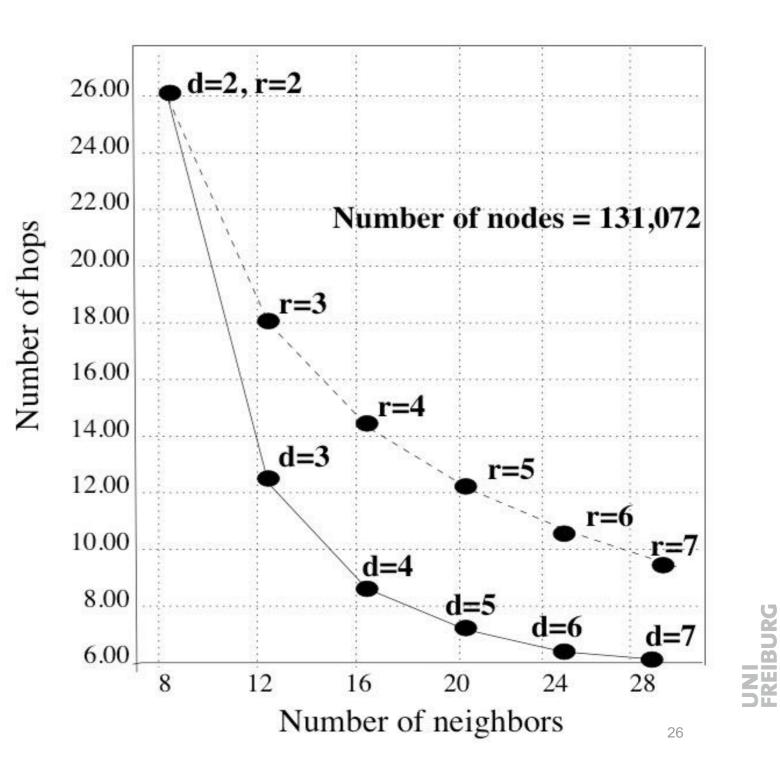

- Dimensionens reduce the lookup path length more effciently
- Realities
 produce more
 robust networks

increasing dimensions, #realities=2

increasing realities, #dimensions=2
