3. Exercise sheet: Petri Nets

Exercise 1
Model a traffic light by a Petri-Net.
(1) You can use any number of places, however only multiplicity 1 is allowed.
(2) Now only 3 places (one for each color) may be used, but there are no restrictions on the multiplicities.

Exercise 2
Prove or give a counterexample: \( m[q]m' \leq m' = m + \Delta q \).

Exercise 3
Model the following Handshaking protocol by a Petri-Net:
Two processes P1 and P2 mutually exchange messages. P1 is the sender and P2 the receiver. P1 starts in state Ready-to-Send. When it has sent a message to P2, it moves into the state Ready-to-Receive and waits for an acknowledgement ACK sent by P2. Once the acknowledgement has been arrived, P1 can send more messages. P2 starts in state Waiting-for-Messages. If it receives a message, it confirms by sending an acknowledgement ACK to P1 and waits for more messages.

Exercise 4
Model the following Reader-Writer synchronization protocol with a P/T Petri Net: There are \( k \) processes that compete for a resource \( p^* \). Only one process is allowed to write to \( p^* \) at a time, but at most \( k \) processes are allowed to read \( p^* \) in parallel.
Motivation

Huge amounts of data...

- New York Stock Exchange generates about 1TB of new trade data per day
- Facebook hosts approx. 10 billion photos ($\sim$ 1PB)
- Internet Archive stores around 2PB of data (with a growing rate of 20TB/month)
- Large Hadron Collider (LHC) will produce around 15PB of data per year

...entail huge challenges:

- Secure, redundant storage?
- Data analysis/handling for $> 1$TB?
- Bottleneck: I/O!

$1$ PB = 1,000 TB

⇒ Cloud Computing to the rescue!
Motivation

Huge amounts of data...

- New York Stock Exchange generates about 1TB of new trade data per day
- Facebook hosts approx. 10 billion photos (∼ 1PB)
- Internet Archive stores around 2PB of data (with a growing rate of 20TB/month)
- Large Hadron Collider (LHC) will produce around 15PB of data per year

...entail huge challenges:

- Secure, redundant storage?
- Data analysis/handling for > 1TB?
- Bottleneck: I/O!

→ Cloud Computing to the rescue!

What is Cloud Computing?

Anonymous

[... ] Unfortunately the marketing guys got hold of the term before the technicians had known what Cloud Computing is [... ]

Larry Ellison

(CEO of Oracle on Cloud Computing)

We’ve redefined cloud computing to include everything we currently do. So it has already achieved dominance in the industry. I can’t think of anything that isn’t cloud computing [... ] The computer industry is the only industry that is more fashion-driven than women’s fashion. [... ] I have no idea what anybody is talking about. I mean it is really just complete gibberish [... ]
Cloud Computing - Definitions

Peter Mell and Tim Grance  
(National Institute of Standards and Technology)

Cloud computing is a model for enabling convenient, on-demand network access to a shared pool of configurable computing resources (e.g., networks, servers, storage, applications, and services) that can be rapidly provisioned and released with minimal management effort or service provider interaction.

C.Baun, M.Kunze, J.Nimis, S.Tai  
(Cloud Computing, Springer 2009)

Building on compute and storage virtualization, and leveraging the modern Web, virtualization, and leveraging the modern Web, Cloud Computing provides scalable, network-centric, abstracted IT infrastructure, platforms, and applications as on-demand services that are billed by consumption.
Cloud Computing Overview

Cloud Computing Essentials

- Pay-as-you-go pricing model
- Build upon virtualization of computing resources
- Minimal management on the user part
- Available and configurable on-demand → High flexibility!

Cloud Computing Flavors

- **SaaS** (Software-as-a-Service): WAN-enabled application services (e.g., Google Apps)
- **PaaS** (Platform-as-a-Service): Foundational elements to develop new applications (e.g., Google Application Engine)
- **IaaS** (Infrastructure-as-a-Service). Providing computational and storage infrastructure in a centralized, location-transparent service (e.g., Amazon EC2)
Cloud Computing Applications

Success Stories

- Animoto\(^1\), a service which automatically generates videos from pictures, achieved a scale up from 50 instances to 3,500 instances in three days.
- Computation to take scanned images from over 60 years online (approx. 4 TB of data) took a weekend on Amazon’s EC\(^2\) using S3 storage service.
- Mogulus\(^2\) streams 120,000 live TV channels without any own hardware, expect laptops.
  → According to CEO IaaS is reason for being in business.

Cloud Computing Evaluation

Benefits

- System scales dynamically, no need to optimize for worst case
- Low total cost of ownership, only operative cost
- Facilitates innovations by low entry barriers & time from idea to system
- Generally: Reduces risks for service users

Open Issues and Limitations

- Legal restrictions, e.g. banking sector
- Security and privacy
- Possible vendor lock-in because of missing standardized APIs
- Generally: What applications work in the cloud? Multiplayer games?

→ Limitations = Open research problems!
Cloud Computing Evaluation

# MapReduce: A Programming Paradigm for the Cloud

## Mission Statement

Make large scale data processing (> 1TB) across 100 - 1,000 CPUs easy

## Key Characteristics

- Automatic parallelization and distribution of workload
- Built-in fault tolerance
- Available status and monitoring tools
- Clean abstraction for programmers
- Borrows ideas from functional programming

→ Open source implementation: [Hadoop](http://hadoop.apache.org/)
Applications of MapReduce

Industrial Applications

- Computation of Google’s PageRank
- Data Mining on large search logs
- Computation of inverted indexes

Research Applications

- HadoopDB (Infrastructure: MapReduce, Nodes: Relational DBMS) [1]
- Distributed RDFS reasoning [8]
- XXX with MapReduce
Review of Functional Programming

Observations

- Functional operations do no modify data structures, they create new ones.
- Original data still exists in unmodified form
  - No synchronization required, if multiple operations are executed, since original data state is still available.
- Data flows are implicit in program design
  - For new data that should be kept, a new name has to be assigned.
- Order of operations does not matter
  - Each operation has its own copy.
Functional Programming Examples

Example I: Function Currying

- fun f(a,b,c,d) = a + b + c + d;
val f = fn : int * int * int * int -> int
- f(1,2,3,4);
val it = 10 : int
→ +(1,2,3,4) = 10
 functional programming examples

example i: function currying cont’ed

- it 2;
val it = fn : int -> int -> int
  \rightarrow (+1, (+2, (+c, d))))
- it 3;
val it = fn : int -> int
  \rightarrow (+1, (+2, (+3, d))))
- it 4;
val it = 10 : int

\[
\begin{align*}
(+) &= (+1, (+2, (+3, 4)))) \\
&= (+1, (+2, 7)) \\
&= (+1, 9) \\
&= 10
\end{align*}
\]
Functions on Lists

Example II: reverse and append

- fun reverse nil = nil |
  reverse(h::t) = reverse(t) @ h::nil ;
val reverse = fn : 'a list -> 'a list
- fun append x nil = x::nil |
  append x lst = reverse(x::(reverse lst));
val append = fn : 'a -> 'a list -> 'a list
- append 5;
val it = fn : int list -> int list
  it [1,2,3,4];
val it = [1,2,3,4,5] : int list
Functions on Lists cont’ed

Example III: *doublist*

- fun doublist nil = nil |
  doublist(h::t) = 2 * h::(doublist t);
val doublist = fn : int list -> int list
- doublist [1,2,3,4];
val it = [2,4,6,8] : int list

Example IV: *inclist*

- fun inclist nil = nil |
  inclist(h::t) = (h+1)::(inclist t);
val inclist = fn : int list -> int list
- inclist [1,2,3,4];
val it = [2,3,4,5] : int list
MapReduce

Example V: map

- fun map f nil = nil |
  map f (h::t) = (f h)::(map f t);
val map = fn : ('a -> 'b) -> 'a list -> 'b list

- val doublist = map (fn x => 2 * x);
val doublist = fn : int list -> int list
- val inclist = map (fn x => x + 1);
val inclist = fn : int list -> int list
- doublist [1,2,3,4];
val it = [2,4,6,8] : int list
- inclist[1,2,3,4];
val it = [2,3,4,5] : int list
MapReduce cont’ed

Parallelism in *map* phase

Computation of $f$ for each element is not dependent on other elements in list.

Example: $inclist[1, 2, 3, 4]$
Functions on Lists cont’ed

Example VI:  \textit{sum}

- fun \textit{sum} \texttt{nil} = 0 \\
  \textit{sum}(h::t) = h + \textit{sum} t;
val \textit{sum} = fn : int list -> int \\
- \textit{sum} \texttt{[1,2,3,4,5]};
val it = 15 : int

Example VII:  \textit{flatten}

fun \textit{flatten} \texttt{nil} = \texttt{nil} | \\
  \textit{flatten} (h::t) = h \@ \textit{flatten} t;
val \textit{flatten} = fn : 'a list list -> 'a list \\
- \textit{flatten} \texttt{[[1,2],[3,4],[5,6,7]]};
val it = [1,2,3,4,5,6,7] : int list
MapReduce

Example VIII: reduce

fun reduce f b nil = b |
  reduce f b (h::t) = f(h, reduce f b t);
val reduce = fn : ('a * 'b -> 'b) -> 'b -> 'a list -> 'b

- val sum = reduce (fn(a,b) => a + b) 0;
val sum = fn : int list -> int
- val flatten = (fn xs => reduce (fn(a,b) => a @ b) nil xs);
val flatten = fn : 'a list list -> 'a list
- sum [1,2,3,4,5]:
val it = 15 : int
- flatten [[1,2],[3,4],[5,6,7]];
val it = [1,2,3,4,5,6,7] : int list
MapReduce cont’ed

Example: $sum \ [1, 2, 3, 4, 5]$

- val sum = reduce (fn(a,b) => a + b) 0;
MapReduce: Programming Model

**map**

\[
\text{map}(\text{in\_key}, \text{in\_value}) \rightarrow (\text{out\_key}, \text{intermediate\_value})
\]

- inputs: records from data source as (key, value) pairs, e.g. (filename, line)
- outputs: one or more intermediate values with an output key

**reduce**

\[
\text{reduce}(\text{out\_key}, \text{intermediate\_value\ list}) \rightarrow \text{out\_value\ list}
\]

- After map phase all intermediate values for one output key are combined together in a list
- reduce combines those intermediate values into one or more final values for the same output key
- In practice, usually one final value per key
Example Scenario

Analysis of sensor readings

- Given is a large amount of sensor readings that are generated automatically and store the temperature at a specific location (e.g., each ms).
- The data is stored in one huge file (> 1TB) in the Google File System and looks as follows:

  ...
  s1  +12
  s2  -10
  s3  -4
  s1  +15
  s1  +30
  ...

→ How can we efficiently determine the maximum temperature for each sensor?
Solution in Java w/ Hadoop

```java
public void map(LongWritable key, Text value,
                 Context context) {
    String line = value.toString();
    String sensor = line1.substring(0, 2);
    String temperature = line1.substring(3, line1.length());
    int temp = -1;
    if (temperature.startsWith("+")) {
        temp = Integer.parseInt(temperature.substring(1,
                                                    temperature.length()));
    } else {
        temp = Integer.parseInt(temperature);
    }
    // (out_key, intermediate_value)
    context.write(new Text(sensor), new IntWritable(temp));
}
```
Solution in Java w/ Hadoop cont’ed

```java
reduce
// (out_key, intermediate_value list)
public void reduce(Text key, Iterator<IntWritable> values,
                   Context context) ... {
    int maxValue = Integer.MIN_VALUE;
    for (IntWritable value : values) {
        maxValue = Math.max(maxValue, value.get());
    }
    // out_value list
    context.write(key, new IntWritable(maxValue));
}
```
System Architecture\textsuperscript{3}

\begin{itemize}
  \item Input key-value pairs
  \item \(S_1\) \(S_n\)
  \item Map
  \item Data store 1
  \item Data store 2
  \item Data store \(n\)
  \item \(\{\text{key 1, values...}\}\)
  \item \(\{\text{key 2, values...}\}\)
  \item \(\{\text{key 3, values...}\}\)
  \item \(\{\text{key 1, values...}\}\)
  \item \(\{\text{key 2, values...}\}\)
  \item \(\{\text{key 3, values...}\}\)
  \item \textbf{Barrier} \textbf{Aggregates intermediate values by output key}
  \item key 1, intermediate values
  \item key 2, intermediate values
  \item key 3, intermediate values
  \item reduce
  \item final key 1 values
  \item final key 2 values
  \item final key 3 values
\end{itemize}

\textsuperscript{3}Picture originally from [2]
Google File System (GFS) ~ Hadoop File System (HFS)

Design Goal

Redundant storage of huge amounts of data on cheap and unreliable machines

Assumptions and (some) consequences

- High component failure rates
  → Replicate data on different machines (usually 3 times)
- Modest (~ 1,000,000 files) number of large (> 1GB files)
  → Increase chunk size to 64MB (on ext3: 4KB!)
- Files are written once, mostly appended to (perhaps concurrently)
  → Add atomic record append operation
- Large in order streaming reads
  → No need for data caching on the client side
- High throughput more important than low latency
GFS/HFS Architecture Overview

File mutations

1. "Open" file for writing/appending
2. Writes go directly to single chunk server, which distributes changes
GFS/HFS Architecture Overview cont’d

Master server duties

- Metadata storage (location of chunk sizes, etc.)
- Namespace management, locking (naming, creating, deleting files)
- Periodic communication with chunk servers
- Chunk creation, re-replication, balancing
- (Lazy) garbage collection: delete log and rename file to hidden name

Problem: Simple Point of Failure & I/O Bottleneck

- Need to keep additional shadow master servers to prevent total failure
- Traffic between client and master server is low (only metadata)
- Updates are done on chunk servers directly
## MapReduce Key Characteristics revisited

### Parallelism
- All *maps* run in parallel
- All *reducers* run in parallel

### Locality
- Maps are instantiated close to the data (ideally on same machine)
- Normal chunk size: 64MB (GFS chunk size)

### Fault Tolerance
- Master detects worker failure
- If failure cannot be resolved, partial results will be returned
## Optimizations

### Bottlenecks

- **Reduce phase cannot start before map phase is finished**
  - Execute slow-running map tasks redundantly and use result of first finished copy

- Transferring map results can be slow due to limited I/O bandwidth
  - Introduce new function type **combine**, which ...
    - Runs on same machine as maps, and
    - Causes mini-reduce phase to occur before real reduce phase
Optimizations cont’ed

Example

- Maximum temperature of a sensor w/o combine:
  - \(map_1: \{(s_1, 12), (s_1, 20), (s_1, 15)\}\)
  - \(map_2: \{(s_1, 23), (s_1, 13), (s_1, 30)\}\)
  - \(\rightarrow reduce: \{(s_1, 12), (s_1, 20), (s_1, 15), (s_1, 23), (s_1, 13), (s_1, 30)\}\)

- Maximum temperature of a sensor w/ combine:
  - \(map_1: \{(s_1, 12), (s_1, 20), (s_1, 15)\} \rightarrow combine_1: \{(s_1, 20)\}\)
  - \(map_2: \{(s_1, 23), (s_1, 13), (s_1, 30)\} \rightarrow combine_2: \{(s_1, 30)\}\)
  - \(\rightarrow reduce: \{(s_1, 20), (s_1, 30)\}\)

MapReduce: A major step backwards
(D. J. DeWitt and M. Stonebraker in The Database Column)

MapReduce may be a good idea for writing certain types of general-purpose computations, but to the database community, it is:

1. a giant step backward in the programming paradigm for large-scale data intensive applications,
2. a sub-optimal implementation, in that it uses brute force instead of indexing,
3. not novel at all – it represents a specific implementation of well known techniques developed nearly 25 years ago,
4. missing most of the features that are routinely included in current DBMS,
5. incompatible with all of the tools DBMS users have come to depend on.
Evaluation of MapReduce

### Pros
- No need to take care of low level aspects, such as synchronization, failure of nodes, message passing, etc.
- Scales (more or less) linearly with the number of machines utilized
- Easy programming model, only map and reduce tasks need to be written

### Cons
- High startup costs (e.g. allocation of nodes), i.e. badly suited for online, interactive tasks
- Not trivial to write and maintain multi-stage reduce jobs
- Not well-suited for heterogeneous data sets, i.e. no native support for joins
Map-Reduce-Merge

Comparison to MapReduce

- Additional merge phase for processing multiple related heterogeneous datasets
- Allows for efficient implementation of joins in parallel environment
- Relationally complete, while keeping the benefits of the MapReduce idea

But...

- Still hard to program, since operating on a low level
Pig (Latin)

Motivation
Data flow language for performing ad-hoc analysis of extremely large data sets

Quick Facts
- Originally developed by Yahoo!, now Apache project
- Imperative-style data flow language
- \((NF)^2\) data model supporting bags, tuples, and maps
- Support for user-defined functions (UDF)
- Compiled to MapReduce jobs
Pig(Latin) Example

Given: DB table urls: (url, category, pagerank)

Query: Return for each sufficiently large category, the average pagerank of high-pagerank URLs in that category.

\[
\text{SELECT category, AVG(pagerank)} \\
\text{FROM urls WHERE pagerank > 0.2} \\
\text{GROUP BY category HAVING COUNT(*) > 1000000}
\]

PigLatin:

\[
\text{good_urls = FILTER urls BY pagerank > 0.2;} \\
\text{groups = GROUP good_urls BY category;} \\
\text{big_groups = FILTER groups BY COUNT(good_urls) > 1000000;} \\
\text{output = FOREACH big_groups GENERATE category, AVG(good_urls.pagerank);} \\
\]

\(^5\)Adapted from [6]
Hive

Motivation

Learning curve for BI users too steep with Pig, which are used to SQL

Quick Facts

- Originally developed at Facebook, now Apache project
- Declarative-style, SQL-like query language
- Data model is divided into three units:
  1. tables ~ relational DB tables
  2. partitions (keys) ~ relational DB indexes (influence data storage)
  3. buckets divide data in each partition based on a hash of some table column
- Data model supports typical primitive types and arrays and maps natively
- Support for user-defined functions (UDF)
- Operates on top of MapReduce & HFS
Hive Example

Given: Hive tables user: (id, gender, age) and page_view: (viewTime, userid, page_url, ip, date)

Query: Return for each user, who visited a URL on March 3rd 2008, the associated page view information, her gender and age

```sql
INSERT OVERWRITE TABLE pv_users
SELECT pv.*, u.gender, u.age
FROM user u JOIN page_view pv ON (pv.userid = u.id)
WHERE pv.date = '2008-03-03';
```

→ The results are always inserted into a table

---

Adapted from [http://wiki.apache.org/hadoop/Hive/Tutorial](http://wiki.apache.org/hadoop/Hive/Tutorial)
Summary

- Cloud Computing lowers entry barriers and allows for massive on-demand scaling of applications with low startup costs.
- MapReduce offers a simple abstraction to parallel computation that is applied to real-world data analysis problems.
- Near future: Blend of research results from different areas, e.g. a blend of distributed computing with database research (already happening: HadoopDB [1]).
